Contents of this report have been approved by the World Agricultural Outlook Board, and the summary was released November 18, 1986. Materials may be reprinted without permission. *Agricultural Outlook* is published monthly, except for the January/February combined issue. Price and quantity forecasts for crops are based on the November '86 World Agricultural Supply and Demand Estimates.

Annual subscriptions: \$26 U.S., \$32.50 foreign. Order from ERS Publications, 1301 New York Ave., NW, Room 228, Washington, D.C. 20005-4789. Make check payable to ERS Publications. You will receive a copy of the current issue and acknowledgement of your subscription order. For further information, call (202) 786-1494. Subscriptions also available from the Government Printing Office. For information, call the GPO order desk at (202) 783-3238.

The next issue of *Agricultural Outlook* (AO-127) is scheduled for mailing on January 8, 1987. If you do not receive AO-127 by January 22, call the managing editor at (202) 786-1494 (be sure to have your mailing label handy). The full text and tables of AO-127 will also be available electronically; additional information on this is available at (202) 447-5163.

# In Brief . . . News of Marketing Loans, Income by Farm Type

Increased slaughter of female stock in the cattle and hog sectors since 1982 has helped hold up red meat supplies, despite declines in animal numbers. However, stronger livestock prices and lower production costs have resulted in improved net returns to livestock producers in 1986. Consequently, red meat supplies are likely to decline further in 1987 as cattle and hog numbers start to stabilize. Total per capita red meat and poultry supplies are expected to be nearly record large in 1986. Per capita consumption from 1970 through 1985 averaged 204 pounds. It peaked in 1985 at nearly 215 pounds and may be slightly lower this year.

Foreign production of all major crops except cotton is again rising in 1986/87. However, U.S. production is lower because of greater participation in Government commodity programs with increased acreage reduction requirements. Total U.S. production of the major field crops this season is forecast to be down 8 percent from near-record-highs a year ago.

As of November 1, U.S. citrus fruit production for 1986/87 was forecast at 12.4 million tons (excluding California's grapefruit outside of the desert areas). This is 14 percent above 1985/86, despite reduced acreage. All citrus crops are forecast higher, primarily because of favorable weather.

Fresh-market vegetable acreage for 1986 is expected to be 2 percent below the 772,000 harvested last year. However, supplies of fresh vegetables are keeping pace with a year earlier and holding the lid on grower prices so far in 1986.

World centrifugal sugar production for 1986/87 is forecast at 100.1 million metric tons, raw basis, up 2 percent from 1985/86's estimated 98.1 million. Cane sugar production is forecast to rise 4 percent and beet sugar production to drop 2 percent.

Net cash income for crop farms is expected to be down in 1986, going from 1985's average \$27,000 per farm to about \$25,000. Government payments to crop farms will rise more than 50 percent, cushioning this year's drop in commodity prices. Lower expenses should save crop farms more than \$3 billion in 1986. For the livestock sector, net cash income per farm may climb more than \$3,500. The average livestock operation, which typically includes some crop production, had cash income of more than \$17,000 this year, because of higher prices, production, and Government payments, and lower expenses.

Under the Tax Reform Act of 1986, the after-tax cost of capital for all farm machinery should increase an average of 11 percent above costs under the current law. The cost of capital for tractors and long-lived equipment should be, respectively,

10.5 and 11.2 percent higher than under the existing law. Because of this, net investment in agriculture during 1986-90 will probably fall below the already negative level which is now occurring.

If marketing loans had been implemented for 1986/87, wheat exports might be only about 30 million bushels higher than without the loans, at a cost of \$8 to \$9 per added bushel. The per-bushel cost of extra corn and soybean exports would also be well above current market prices.

A large-scale acreage reduction program designed to idle 125 million acres, or about half of the program acreage base, could raise U.S. farm prices 30 to 40 percent above 1985/86 (by comparison, the 1986 program idled about 44 million acres). As a consequence, Government outlays for price and income supports would fall to nearly zero after several years, and farmers' net cash income would probably rise. In contrast, outlays for fiscal 1986, which include advance deficiency and dairy termination payments, totaled \$25.8 billion.

However, large farm price increases would likely reduce U.S. farm exports 30 to 50 percent. Also, the mix of foods purchased by domestic consumers would shift away from more expensive high-value products in response to a 30-35 percent rise in retail food prices. These declines would cut agriculture's contribution to U.S. GNP by \$50 to \$75 billion per year. As many as 2 million jobs might be lost on farms and in the inputs and marketing industries.

With U.S. planted acreage expected to fall again in 1987/88 under the 1985 Farm Act, the outlook for the inputs industries remains weak. Employment dropped an average 10 percent a year during 1982-84 in the fertilizer industry, 11 percent in the farm machinery industry, and 4 percent in the pesticide industry.

## Agricultural Economy

### LIVESTOCK OVERVIEW

Increased slaughter of female stock in the cattle and hog sectors since 1982 has helped hold up red meat supplies, despite declines in animal numbers (table 16). However, stronger livestock prices and lower production costs have resulted in improved net returns to livestock producers in 1986. Consequently, red meat supplies are likely to decline further in 1987 as cattle and hog numbers start to stabilize. Total per capita red meat and poultry supplies are expected to be nearly record large in 1986 (table 10). Per capita consumption from 1970 through 1985 averaged 204 pounds. It peaked in 1985 at nearly 215 pounds and may be slightly lower this year.

Poultry production continues to expand, with producers exploiting poultry's shorter biological cycle to respond to low prices. In light of expected lower supplies of competing red meats in 1987, poultry production may rise 8 percent. However, meat prices probably will remain under some pressure, since total supplies will be at record levels and the economy is still expanding only moderately.

Poultry products such as nuggets and strips have been introduced into many more restaurants this year, boosting broiler prices more than might have been expected, given the continued general production increases. Hot weather this summer added to price

strength; the heat caused concerns over supplies, as some bird deaths and slower weight gains held down production increases. Declining feed costs this year and higher poultry prices, particularly last summer, resulted in further improvement in already positive net returns.

Hog producers' returns increased dramatically this summer. The hog-corn ratio, a general measure of profits to hog producers, reached the highest since the data series began in 1909. Profitability in hog production normally leads to an expanded breeding herd and year-over-year increases in sows farrowing about two quarters after profitability sets in.

However, hog producers' response to the higher returns in 1986 may be moderated by recent financial difficulties. Stricter bank lending requirements may force the continued marketing of female stock to improve the debt-equity ratio on many farms.

Pork production in 1986 may be down about 5 percent from a year earlier, with second-half output down about 7 percent. As pork supplies declined through summer, prices rose sharply from \$43 per cwt in the first quarter, to \$47 in the spring, to a peak of \$61 during the summer. Fall-quarter prices declined to \$53 to \$56 but likely will average about \$10 above last fall. For all of 1986, prices will average \$51 to \$52, up from near \$45 in 1985.

The cattle industry has likely reached an end to its extended inventory adjustment. The January 1, 1987, cattle inventory may total about 100 million head, down from about 102 million a year earlier. But, lower feeding costs, a record-large hay crop, and much improved forage conditions will provide a base to stabilize the inventory over the next couple of years, so the January 1, 1988, figure may still be close to 100 million head.

Net returns to cattle feeders and cow-calf operations have increased, and both have likely covered cash costs in 1986. Herd reductions since 1982 and the sixth consecutive decline in the calf crop this year are likely to result in sharply reduced beef supplies in the future. Feeder cattle supplies outside feedlots on October 1 were down 7 percent from a year ago; the yearling supply was down 17 percent.

### Per Capita Meat Consumption Staying Near Record High

Fed and nonfed beef supplies for 1986 remain large. Beef production this year is likely to be about 2 percent above 1985, largely because of the increased dairy cattle slaughter under the Dairy Termination Program (DTP). However, Government purchases of beef and other meats have largely offset increased supplies from the DTP. The first DTP period ended in August and with it ended the largest impact on the beef industry from the program.

Fed cattle marketings in 1986 remain near levels of the past several years. Some additional female stock is expected to be retained over the next couple of years, but any herd expansion will be very slow. Thus, fairly large numbers of heifers will continue to be available for feedlot placement.

Prices for Choice fed steers at Omaha increased from \$54.52 per cwt this spring to near \$60 in early fall. Prices for 1986 as a whole may average about the same as 1985's \$58.37. With lower feed costs, feeder steer prices have strengthened along with fed cattle prices. However, prices for yearling feeder steers at Kansas City this year may average near a year ago. Prices this summer averaged about \$3 per cwt above a year earlier and are maintaining a \$3 to \$4 premium this fall.

Utility cow prices at Omaha continue to average \$37 to \$38 per cwt. Prices

## Production of Livestock and Products

declined to the low \$30's in early April over concern about the impact of the DTP. However, prices strengthened and remained fairly stable through early fall, as Government meat purchases offset the DTP supplies.

Poultry production in 1986 is expected to be 6 percent above a year earlier (table 13). Broiler production may rise about 4 percent, the same as a year ago. Production was up only 3 percent this summer, compared with a 5-percent year-to-year gain this past spring and an expected 4-percent rise this fall. Without the heat, production might have been somewhat larger this summer.

Turkey production is expected to be up 12 percent in 1986, following no change in 1984 and a 9-percent gain in 1985. Turkey stocks at the beginning of the fall holiday season were the third largest since 1960, with whole-bird stocks up 16 percent from a year earlier. With both production and stocks up, available fourth-quarter turkey supplies will be up sharply from a year ago.

The 12-city broiler price this fall is expected to average 54 to 57 cents per pound, well above last fall but down from the record 66.6-cent average this summer. For the year, broiler prices may average 56 to 57 cents a pound, up from 50.3 in 1985. Turkey prices this fall are likely to average about

the same as the summer quarter's wholesale New York average of 79.8 cents. For the year, prices may average 72 to 73 cents a pound, down from 75.5 in 1985.

Egg production in 1986 is likely to be about the same as a year ago. Consumption will probably total around 252 eggs per person, down from 255 last year, continuing the long downward trend. For the year, wholesale egg prices at New York may average 70 to 71 cents a dozen, up from 66.5 cents a year earlier.

After sizable summer rises, wholesale prices of dairy products have been

## Lower Prices Help Push Up Boller Consumption

Cents per pound<sup>1</sup>

1986 estimated; 1987 forecast.

<sup>1</sup>Wholesale price, 12-city average, 1982 dollars.

<sup>2</sup>Ln consumption = 6.952-0.774 (Ln price).

fairly steady since early September (table 14). Butter prices stayed near the level at which the CCC will sell butter back to the industry. Increased supplies of cream from the fluid milk industry eliminated the need to buy from Government stocks but have not been sufficient to lower prices. American cheese prices have firmed but remain near late-summer levels. Prices of nonfat dry milk held steady during the summer but edged up about a penny a pound in October.

The 1986 seasonal increases in wholesale prices have been similar to those in most years of the 1970's. Reductions in milk output because of the Dairy Termination Program, continued growth in commercial use, and low commercial stocks reestablished a balance in commercial dairy markets—at least temporarily. Some further increases in cheese and nonfat dry milk prices are possible as the tightest season nears, but additional rises probably will be small.

The Minnesota-Wisconsin (M-W) price of manufacturing grade milk, the basic mover of most farm milk prices, has followed wholesale dairy product prices upward. In October, the M-W price was \$12.69, up 71 cents from May and 48 cents above a year earlier. The October M-W price will determine the December price of milk used for fluid milk products.

The average price of all milk was \$13 in October, up \$1.10 from June and \$1.40 higher than a year earlier. The increase in the average price reflected part of the seasonal rise in the M-W price, as well as seasonal increases in the fat content and a greater proportion of milk going to more expensive fluid use.

Seasonal declines in farm and wholesale prices will be sharp this winter. The seasonal return to surplus conditions will combine with a January 1 lowering of the support price to \$11.35 per cwt to drop prices by late winter. However, the surplus is not expected to be as large as in most recent years, and the M-W price may stay closer to the support price. [Ron Gustafson, Allen Baker, Leland Southard, and James Miller (202) 786-1830]

## CROPS OVERVIEW

Although the rate of growth has slowed, foreign production of all major crops except cotton is rising again in 1986/87 (table 25). However, U.S. production is lower because of greater participation in Government commodity programs with increased acreage reduction requirements (table 17). Total U.S. production of the major field crops this season is forecast to be down 8 percent from near-record highs a year ago.

Increased foreign production and lower commodity prices are boosting world consumption of all crops. Stocks of corn, soybeans, and wheat will remain high by historical standards, though, maintaining downward pressure on commodity prices.

Lower U.S. prices allowed by the 1985 Farm Act are enhancing export potential, particularly for cotton and rice. For those crops, the United States may capture much of the gain in world trade volume this year.

Lower world prices are resulting from

- reduced loan rates;
- cotton and rice marketing loan programs, in which producers may repay CCC loans at less than the original loan rate; and
- the freeing up of Government-obligated commodities through generic certificates, issued mainly as partial payment for farmers' participating in commodity programs.

Also, increased acreage reduction requirements, paid land diversion programs, and the Conservation Reserve Program are reducing domestic production capacity. Still, without a major shortfall in world crop output, most world and domestic commodity supply/demand imbalances will not significantly improve soon.

Large food grain crops will be harvested worldwide in 1986/87, despite lower U.S. production. Global rice output is projected at 318 million tons (milled basis), while the world's wheat crop will be the largest on record—514 million tons. Stocks will remain well above historical averages and may be a record for wheat in 1986/87.

Foreign crops of wheat and rice are projected to gain 6 and 1 percent, respectively, in 1986/87. Foreign wheat production will be a record 457 million tons, while rice output of 314 million will be just short of the record.

Gains in foreign consumption are leading to a small increase of 2 million tons in world wheat imports. But the 1986/87 import total of 87 million tons (excluding intra-EC trade) is still about 16 million below the average when world trade was at its peak in 1981/82-1984/85. Increased wheat imports are going to Latin America (particularly Brazil) and Africa. In 1987, without the record Brazilian imports, world rice trade will drop.

Halfway through the U.S. marketing year for wheat, despite the smallest harvest in 6 years and a 10-percent increase in total disappearance over a year ago, wheat prices on the farm are the lowest in 9 years (table 18). Large domestic supplies, due to record carryin stocks, are keeping prices down.

Although three-fourths of total domestic wheat stocks are isolated from the market, some Government-obligated stocks are being freed by generic certificate exchanges. Since April 1986, certificates have been issued to farmers through program payments and to grain merchants through the Export Enhancement and Targeted Export Assistance programs. By October, however, improved Durum wheat exports, the reduced forecast for the 1986 Soft Red Winter harvest, and delayed seeding of next season's winter wheat crop lifted prices above the loan rate for these classes.

For the other wheat classes (Hard Red Winter, Hard Red Spring, and White),

## 1987 Crop Program Provisions

Provisions for 1987 crop programs have been announced. General provisions include the following:

- Marketing loans and certificates are given for cotton and rice.
- A producer may reduce permitted planting (base minus ARP and PLD) by 8 to 50 percent and still get deficiency payments as if 92 percent were planted.

- Limited cross compliance is in effect—a producer must plant within base acres on other crops.
- The State Agricultural Stabilization and Conservation committee can okay grazing but no haying some months on ARP land, and can allow both haying and grazing on underplanted land.

Loan rates, target prices, and other provisions are as follows:

### WHEAT

	1986	1987
Loan rate (\$/bu.)	2.40	2.28
Target price (\$/bu.)	4.38	4.38
Acreage reduction prog. (%)	22.5	27.5
Paid land diversion (%)	2.5	0

Percent of advance paid in certificates	25	50

## World Wheat & Coarse Grain Consumption in 1986/87 Close to Trend

Million metric tons

1986/87 consumption forecast

<sup>1</sup>Trend consumption =  $-758.3 + 24.2$  (year).

prices have languished because of large supplies and lower-than-expected loan placements of new-crop wheat. Overall, prices are not expected to rise much as the marketing year progresses, unless 1987/88 winter wheat seeded acreage falls below expectations or poor weather through next spring damages the crop.

Wheat plantings for 1987 could fall slightly because of increased program participation and a rise in the acreage reduction requirement from 25 to 27.5 percent. Rice plantings are projected to gain slightly, with the acreage reduction requirement constant at 35 percent of base and program participation anticipated to be around 95 percent.

World coarse grain production in 1986/87 is forecast at 830 million tons, 17 million below last season's record, but well above projected world utilization. So, world ending stocks are expected to increase again.

Foreign production is projected at 580 million tons, up 7 million from 1985/86. Larger crops in China, South Africa, and Canada are offsetting smaller production in Western Europe and Thailand. Foreign corn output has gained 14 million tons to a record 270 million. Despite a record Canadian barley crop, foreign barley production is off slightly because of a 9-percent drop in the EC.

Foreign Wheat & Coarse Grain Output  
Rase Sharply Until 1984/85

Foreign coarse grain utilization will likely expand by under 2 percent during 1986/87. This gain exceeds the growth of production; however, foreign stocks will increase slightly and foreign imports may rise marginally to 85 million tons (excluding intra-EC trade).

U.S. exports are expected to expand by about 4 million tons; larger shipments by Canada (barley) and South Africa (corn) also are projected. Despite these gains, world trade remains depressed compared with the first half of the 1980's. Much of the recent drop is due to lower Soviet imports—1986/87 USSR imports are down about 15 million tons from 2 years ago.

The 1987 U.S. feed grain program requires participating farmers to reduce acreage by 20 percent of their base to be eligible for price supports and other program benefits. Also, the Government is offering to pay farmers extra to divert an additional 15 percent of their acreage to conserving uses. The 15-percent diversion is not required to be eligible for target price protection and nonrecourse loans, but most feed grain farmers will find the extra payment attractive and will leave 35 percent of their acreage idle. The 1986 acreage reduction and paid land diversion programs totaled 20 percent.

Per-bushel diversion payments for grain that otherwise would have been grown will be \$2 for corn, \$1.90 for sorghum, \$1.60 for barley, and 80 cents for oats. Participants may receive 40 percent of the estimated deficiency and half of the diversion payment in advance. Fifty percent of the payment will be in cash and the other half in generic certificates.

Sign-up for next season's feed grain programs will run from November 17 through March 30. Target prices for the feed grains will not change from last year, but effective loan rates will be lower—\$1.82 for corn, \$1.74 for grain sorghum, \$1.49 for barley, and 94 cents for oats.

Feed grain plantings next spring should fall significantly from a year earlier, with higher program participation, an increase in the set-aside requirement, and a strong response to the voluntary paid diversion program. Oat area, however, should rise significantly as farmers increase use of oats as a cover crop on idled conserving use acreage.

Record output of soybeans, peanuts, and rapeseed is expected to push world oilseed production in 1986/87 to a new high of 198 million tons. Bigger foreign production will more than offset a projected 7-percent decline in U.S. output. While world oilseed crush will increase, ending stocks of oilseeds will rise more than 13 percent. Soybean and rapeseed stocks will hit records (table 21).

Despite an expected rise in U.S. soybean meal stocks, larger world meal consumption will drive world ending stocks of all meals to their lowest level in 4 years. But, world oilmeal trade will show little growth. Since no significant gains in world soybean meal trade are likely and Southern Hemisphere supplies will increase, U.S. soybean meal exports are likely to decline 2 percent.

Large supplies of edible oils will keep world market oil prices depressed. Palm oil production is up again and is expected to account for the largest share of world vegetable oil exports for the third consecutive year. U.S. soybean oil shipments are likely to decline for the fifth consecutive year.

Monthly soybean prices in Central Illinois fell from an average of \$5.15 a bushel in July to \$4.50 in October, reflecting the drop in the 1986 loan rate to \$4.77. Prices are not expected

to rise much during the marketing year. Both domestic crush and exports are forecast to move up slightly in 1986/87. But, with the 2.01-billion-bushel crop surpassing expected disappearance, ending stocks likely will rise 15 percent to 615 million bushels.

The world glut of cotton is beginning to ease in 1986/87 as production falls and consumption rises, but ending stocks will remain excessive. World production is forecast to fall 9 percent to 72 million bales, the lowest since 1983/84's 68 million.

Consumption will reach a fifth consecutive record, rising more than 3 percent to 77 million bales. Exports also will expand by 2.6 million bales, a 13-percent increase. Global stocks will fall from 48 million bales to 42 million by the end of the season, but they still will be well above the 20-25 million bales common prior to 1984/85.

Foreign production will drop 3 million bales while consumption grows a healthy 3 percent. Thus, foreign stocks at the end of 1986/87 will be down 5 percent below 1985/86. Foreign exports likely will drop 2.2 million bales as the U.S. market share rebounds to a more normal 29 percent. The United States is expected to account for two-thirds of the worldwide reduction in stocks this year (table 19).

A major goal of the farm bill's cotton provisions is to reduce domestic stocks to about 4 million bales over the next 5 years. The 1986 cotton program initially was expected to lower stocks 25 percent to 7 million bales. However, stronger-than-expected domestic use, a more than threefold rise in exports, and a smaller crop likely will lower carryover stocks further than that. Based on November 1 crop estimates, 1986/87 carryover is projected to fall 40 percent to 5.6 million bales, only 1.6 million above the target.

Domestic plantings in 1987 may exceed 1986's 9.5 million acres. Participation in the 1987 cotton program is anticipated to fall slightly because of stronger marketings and the recently announced \$250,000 limit on total program payments. [Michael Hanthorn (202) 786-1840 and Frederic Surlis (202) 786-1691]

U.S. Citrus Production  
Rebounding from Freeze Damage

As of November 1, U.S. citrus fruit production for 1986/87 was forecast at 12.4 million tons (excluding California's grapefruit outside of the desert areas). This is 14 percent above 1985/86, despite reduced acreage. All citrus crops are forecast higher, primarily because of favorable weather.

Because the economy is growing only slowly, domestic demand for fresh citrus fruit will probably be stable. Export prospects for U.S. oranges and grapefruit are likely to improve because the prices are expected to be lower than last season and the dollar has weakened against some currencies. Strong movement of frozen concentrated orange juice (FCOJ) will maintain processor demand for oranges. But, processor demand for grapefruit is not expected to be as strong as last season in view of larger carryover stocks of most grapefruit products.

The 1986/87 output of FCOJ in Florida should exceed last season's 132 million gallons because of the larger orange crop and higher juice yield. The first forecast for 1986/87 yield is 1.44 gallons a box at 42.0 degrees Brix, compared with 1.33 last season. Domestic supplies will still be small because of expected lower carryin stocks. To meet domestic demand, FCOJ imports will remain relatively heavy.

However, the recent preliminary ruling by the Department of Commerce that Brazilian FCOJ is being exported

to the United States at less than fair value may lower imports during 1986/87 or make them more expensive. The final decision on an additional tariff is scheduled no later than March 9, 1987. After Brazilian exporters recently raised prices on their FCOJ, Florida packers also raised prices, going from \$3.84 to \$4.08 per dozen 6-ounce cans (unadvertised brand, f.o.b. Florida canneries). This compares with \$4.60 a year ago. If demand continues steady, prices are likely to remain firm.

Fresh-market vegetable acreage for 1986 is expected to be 2 percent below the 772,000 harvested last year. However, supplies of fresh vegetables are keeping pace with a year earlier and holding the lid on grower prices so far in 1986 (table 23).

Area for harvest of the major fresh-market vegetables during the fall is estimated at 136,200 acres, near last season. Lettuce acreage, which accounts for approximately 37 percent of all fall acreage, dropped 1 percent to 50,200.

California has 82 percent of lettuce acreage, with the majority of the fall area in the central coast region. California lettuce growers reduced acreage about 1 percent from last year to 41,000, while Arizona and Florida dropped acreage 8 percent to 6,000. If lettuce supplies remain level with last year, prices are likely to stay strong for the remainder of 1986, averaging around \$12.00 per cwt.

Florida's total winter vegetable acreage was steady with last year. Tomato acreage for this fall rose 31 percent to 15,700, while sweet corn acreage dropped 23 percent to 9,300. Grower prices for sweet corn are lower than normal this fall because of large summer supplies, which encouraged some growers to switch to alternative crops.

The 1986 average index of grower prices for fresh-market vegetables is likely to be 1 to 2 percent above last season's 125 (1977=100). Most of the price strength comes from smaller lettuce supplies during the second quarter—down 10 percent from a year earlier. Supplies for the fourth quarter appear to be comparable with last year's 47 million cwt. Fourth-quarter prices usually rise about 5 to 10 percent over the third quarter as vegetable production becomes centered in Florida and California.

The November 1 Crop Production report indicated that U.S. dry bean production will be 22.7 million cwt. near last year's 22.3 million. This is a 17-percent downward revision since August, the drop due to heavy rains and flooding that hit the Midwest during September.

World centrifugal sugar production for 1986/87 is forecast at 100.1 million metric tons, raw basis, up 2 percent from 1985/86's estimated 98.1 million. Cane sugar production is forecast to rise 4 percent and beet sugar production to drop 2 percent.

Rising output in Brazil and Asia accounts for almost 70 percent of the cane sugar increase. Falling production in the EC and the USSR accounts for most of the lower beet sugar forecast.

World sugar consumption for 1986/87 is forecast at 99.7 million metric tons, up 2 percent from 1985/86's 97.7 million because of higher consumption in Asia, Africa, and South America. U.S. consumption is forecast to decline about 145,000 tons.

The forecast world production and consumption will mean an addition to world stocks in 1986/87 for the sixth consecutive year. The world price averaged only 5.42 cents a pound in October.

U.S. beet and cane sugar production in 1986/87 is forecast at 6.4 million short tons, raw value, up 5.6 percent from last season (table 24). The November forecast for 1986-crop sugarbeet production is 24.8 million tons, up 9.4 percent from last year. Heavy rains in Michigan have reduced both acreage and yields from earlier forecasts. U.S. sugarcane area is forecast at 801,400 acres, up 4.1 percent from last year, mostly because of a 10-percent acreage increase in Louisiana. U.S. raw sugar prices (Contract No. 14, nearby futures) averaged 21.4 cents a pound in October and 20.46 cents a pound in 1985/86. (Ben Huang, Shannon Hamm, and David Harvey (202) 786-1770)

## COMMODITY SPOTLIGHT

### What Would Marketing Loans Cost For Wheat, Corn, and Soybeans?

The 1985 Farm Act gives the Secretary of Agriculture discretion to allow farmers to repay their price support loans at less than the original loan rates. The resulting "marketing loans" could under certain conditions lower U.S. crop prices and enhance exports. U.S. grain exports are forecast to rise during 1986/87 even without marketing loans, but not by enough to significantly reduce stocks. Consequently, it has been suggested that marketing loans be implemented for wheat, feed grains, and soybeans.

Interest in marketing loans is being piqued by the extraordinary rise in 1986/87 cotton export commitments (shipments to date plus outstanding sales). Because of much lower prices this year, and reduced exports last year in anticipation of lower prices, cotton export commitments in 1986/87 are more than 240 percent above 1985/86.

In contrast, wheat export commitments are only 11 percent higher than a year ago, soybeans are 21 percent higher, while feed grain commitments are actually 22 percent lower. Would the performance of grain and soybean exports match that of cotton under a marketing loan program? What would the costs be?

#### Significant Costs

If USDA had established a marketing loan for the other six crops eligible under the 1985 Farm Act (wheat, corn, grain sorghum, barley, oats, and soybeans), crop-year net lending would have totaled an additional \$1.8 billion for 1986 programs. About 80 percent of the additional outlay would have been for corn and soybeans.

Marketing loans keep regular loan rates from becoming price floors for program crops. Implementation requires USDA to establish a formula for defining a commodity's world market price and to announce that price periodically.

For wheat and feed grains, a farmer would repay a support loan at the prevailing world price or 70 percent of the basic loan rate, whichever was higher, or a loan deficiency payment could be offered in lieu of placing grain

### Cotton Export Commitments More Than Triple a Year Ago...

### ... While Wheat Export Commitments Are Up Only 25 Percent

Commitments equal outstanding sales plus actual shipments.

under loan. For soybeans, the repayment rate would be the lower of the announced world price or the effective loan rate.

Take wheat as an example. The Farm Act set the basic loan rate for 1986 at \$3 per bushel and gave the Secretary authority (which was exercised) to reduce this amount by 20 percent to \$2.40. With the 4.3-percent Gramm-Rudman-Hollings reduction,

the effective loan rate for wheat this marketing year is \$2.30 per bushel—the amount farmers will repay when redeeming 1986 loans without certificates. Implementation of a marketing loan, however, would lower the repayment rate to the higher of the announced world market price or \$2.10 (70 percent of the \$3 basic loan rate).

Net marketing loan outlays (\$ mil.)	103
<b>Total net marketing loan outlays (\$ mil.)</b>	<b>1,836</b>

\*Reflects a 4.3-percent Gramm-Rudman-Hollings reduction.

### Forecast Results of the Farm Act During 1986/87

Crop	Ex-ports	Price supports*	Change from	Ratio
			1985/86	In
Percent				
Wheat	12	-43	-0.28	
Corn	5	-39	-0.12	
Soybeans	3	-10	-0.27	

\*Wheat: \$2.30 from \$3.30;  
Corn: \$1.84 from \$2.55;  
Soybeans: \$4.56 from \$5.02.

For wheat and feed grains, the amount of grain eligible for a marketing loan would be the production on farmers' program acreage. Total eligible wheat in 1986/87 would be an estimated 1.64 billion bushels.

With the \$2.10-a-bushel repayment rate, gross outlays for a wheat marketing loan this marketing year would be about \$320 million (1.64 billion bushels times the 20-cent difference). A world price above \$2.10 would reduce the program's cost. For this analysis, it is assumed that loan deficiency payments would not be made. Additionally, actual marketing loan outlays would be the gross outlays minus program cost savings due to both reduced loan forfeitures and lower Government storage costs.

For this exercise, it is assumed that increased commodity exports resulting from marketing loan-induced price reductions would be satisfied by redeemed grain that otherwise would be

forfeited to CCC at \$2.30 per bushel. It also is assumed that reduced forfeitures would lower CCC storage costs 35 cents per bushel. Therefore, the net marketing loan outlay for wheat in 1986 would be about \$250 million (the \$323-million gross outlay minus the total per-bushel saving of \$2.65 multiplied by the projected increase in wheat exports resulting from the marketing loan).

With soybeans, since there are no acreage reduction requirements for farmers receiving a price support loan, the entire crop could be eligible for a marketing loan. The maximum possible cost of a soybean marketing loan for 1986 would be about \$560 million (the difference between the \$4.56 effective loan rate for 1986/87 and an assumed world price of \$4.25 per bushel, times the 2.01-billion-bushel crop, minus the \$73-million savings from reduced placements and storage costs). It is assumed that all loans are repaid.

### Impact on Exports This Year

A marketing loan for wheat or feed grains essentially would establish a price floor closer to the loan repayment rate, which is 70 percent of the basic loan rate. This means grain programs still would not work the same as the cotton program. For 1986/87, the Government is making U.S. cotton prices competitive on world markets by giving cotton buyers certificates which bridge the entire gap between the loan repayment rate and the world price. Since there is essentially no lower limit on U.S. cotton prices, USDA can reduce domestic prices for cotton more than it can for wheat and feed grains via marketing loans.

For soybeans, however, the loan repayment rate would be set at the lower of the effective loan rate or the prevailing world price. Consequently, a marketing loan program for soybeans could lower domestic soybean prices by however much was needed to meet world competition.

Marketing loans likely would not have had a major impact on U.S. exports this season (1986/87). The additional drop in prices would not be great compared with the percentage declines that already are occurring between 1985/86 and 1986/87.

Possible Effects of Marketing Loans on 1986/87 Exports

	Wheat	Corn	Soybeans
Change in price support* (%)	-10	-10	-7

Assumed ratio of exports to price support	-.84	-.72	-.81
Net outlays (\$ mil.)	98	748	412
Absolute change in exports (mil. bu.)	85	99	45
Cost per bushel (\$)	1.15	7.60	9.25

Large carryin stocks, the big corn crop, lower loan rates, and increased free stocks from generic certificates since April already have significantly lowered domestic corn and wheat prices. And, the Export Enhancement Program has lowered U.S. grain export prices further. Moreover, large world supplies of most agricultural commodities and lagging Soviet purchases are making it difficult to increase U.S. agricultural exports in the near term.

**Cost of Added Exports Under Current Assumptions**

The assumptions made about how exports would respond to lower prices are critical in estimating per-bushel

marketing loan costs. Current U.S. trade estimates for 1986/87, without marketing loans, indicate that wheat exports are rising about 12 percent as the wheat price support is dropping 43 percent, for an export change-to-price change ratio of .28. If that relationship held, marketing loans might boost wheat exports about 30 million bushels this season, to about 1,055 million. With the same type of assumptions for corn and soybeans, marketing loans would increase their exports about 15 million bushels each.

Under these assumptions, the cost of a marketing loan program per bushel of increased exports would probably be very high, because the additional subsidy would be paid on all bushels eli-

gible for price support loans, not just on those exported. If a marketing loan program for wheat cost about \$250 million in 1986/87 and exports rose about 30 million bushels, the cost for the additional exports would be between \$8 and \$9 per bushel. Currently, cash prices for wheat in Kansas City are about one-third that.

A marketing loan program for corn could cost over \$50 per bushel of increased exports, roughly 35 times the market price. A marketing loan program for soybeans could cost over \$35 per bushel of added shipments, about eight times current market prices.

**Cost of Added Exports Under Different Assumptions**

Several factors other than U.S. price supports affect exports: the strength of the dollar, foreign production, foreign economic growth, and long-term trade agreements. Furthermore, the effects of lower U.S. prices on foreign production and consumption are likely to become more pronounced over time. Consequently, the effectiveness of a marketing loan program implemented over several years could be greater than current estimates for 1986/87 would indicate.

The above ratios of the change in exports to the change in price supports are lower than would be expected for 1986/87 if a change in U.S. price supports were the only factor in the outlook. This season, the absence of Soviet buying, in particular, is holding down the export response to lower prices. Trying to boost U.S. exports in the current environment of large world supplies is like trying to push a chain uphill. But conditions will eventually change.

If the export responses to lower prices were twice this season's indicated ratios for wheat and soybeans and three times this season's indicated ratio for corn, then implementation of a marketing loan program would boost wheat exports nearly 60 million bushels, corn exports about 50 million, and soybean exports 30 million bushels. The added exports would not affect gross marketing loan outlays, but loan forfeiture and storage cost savings would be two times current indications for wheat and soybeans and three times for corn.

Consequently, net marketing loan outlays would drop to about \$170 million for wheat, \$860 million for corn, and \$485 million for soybeans. This would mean that the net cost of a marketing loan program for wheat would drop from \$8-\$9 per bushel of increased exports to about \$3. The cost for corn would drop to about \$17, and soybeans would drop from more than \$35 per bushel to about \$16. If the export response to lower prices were even greater, the per-bushel costs would drop still further.

As the ratio of export change to wheat price support changes rises to 3 times current indications, the per-bushel cost of a wheat marketing loan program drops below current market prices. In contrast, even if the ratios for corn and soybeans are assumed to be more than four times this season's indications, the per-bushel net costs would still remain above current market prices.

Thus, a marketing loan program could be more cost-effective for wheat than for corn and soybeans. The ratio of the current marketing-year forecast for exports to new-crop grain eligible for subsidy is 0.63 for wheat, but only 0.21 for corn and 0.38 for soybeans. A marketing loan would lower prices paid for bushels used domestically, as well as for bushels exported. Since wheat exports account for a larger share of total use, a marketing loan subsidy would benefit wheat exports more than either corn or soybeans. *[Michael Hanthorn (202) 786-1841 and Terry Townsend (202) 786-3313]*

## Farm Finance

Advance crop deficiency and feed grain diversion payments for 1987/88 could potentially add \$1 billion to calendar 1986 direct Government payments to farmers. However, the percentage of advances actually received during 1986 will likely remain small, because of the long sign-up period, farmers' tendency to contemplate programs at length before deciding on participation, and tax considerations. A portion of these payments advanced in calendar 1986 would normally have appeared in farm income as late as calendar 1988.

Farm production expenses are expected to be down 5 percent in 1986 as both input use and prices decline. Expenses for interest, fuels, fertilizer, land rental, and seed have probably decreased the most. Substantially lower interest rates and fuel prices are saving farmers nearly \$4 billion.

Interest rate and fuel cost declines also lower costs for input suppliers, ultimately leading to savings on input prices. For example, the decline in energy prices could cut farmers' fertilizer expenses \$1 billion per year in 1986 and 1987. Lower input prices should reduce the prices paid index for all production inputs by 3 percent this year.

Receipts from commodities directly supported by Federal programs totaled 46 percent (\$65.5 billion) of total cash

receipts in 1985. With receipts from program commodities off roughly 15 percent in 1986, total cash receipts could exhibit the largest percentage decline since 1949. However, when direct payments of about \$13 billion (including nearly \$4 billion in marketing certificates) are combined with a \$6- to \$7-billion decline in cash expenses, net cash income should end up near 1985's \$39.5 billion (in constant dollars). Because of higher prices, livestock farms are expected to receive 48 percent of all 1986 cash income, up from 40 percent in 1985.

Net farm income, a measure of net value of agricultural production, is expected to decline in both current and constant dollars, mainly because of less total farm output (down 5 percent) and lower prices received (down about 4 percent).

## 1985 INCOME DISTRIBUTION BY TYPE OF COMMODITY

Aggregate income measures do not allow ready assessment of earnings by different types of farms, such as wheat, rice, cotton, or dairy operations. Because different farm types use different production practices and make unique decisions on financing, marketing, purchasing, and Government program participation, changes in any of these will affect specific farm types differently.

In the past, USDA has relied on the Census of Agriculture, which is published every 5 years, for information on income by type of farm. Now, USDA is putting greater emphasis on its own Farm Costs and Returns Survey (FCRS).

The FCRS indicates that the distribution of crop receipts between crop and livestock farms in 1985 was almost a mirror image of 1982. Crop farms accounted for 91 percent of crop sales in both years. Enterprises such as nurseries and those growing crops such as cotton, fruit, and vegetables were even more specialized. However, the 1985 data indicate slightly higher sales of cattle and hogs on crop farms than in 1982. Dairy farms, which require specialized investments, continued to make only 2 percent of cash sales in 1985.

In 1985, crop farms received about 76 percent of direct Government payments, with livestock farms receiving

### Cost of Capital Under Current and New Tax Law

#### Capital Costs Rising From Tax Law Changes

Under the Tax Reform Act of 1986, the after-tax cost of using capital to purchase farm machinery should increase an average of 11 percent above costs under the current law. The cost of using capital for tractors and other long-lived equipment should be, respectively, 10.5 and 11.2 percent higher than under the existing law. Because of this, net investment in agriculture during 1986-90 will probably fall below the already negative level which is now occurring.

The tax changes will be phased in during 1986 and 1987. For 1986, the only change will be the elimination of the investment tax credit. Therefore, those assets which were eligible for the investment tax credit (all assets except multipurpose structures) will now cost about 10 percent more.

In 1987, the lower marginal tax rates and new depreciation system become effective. These two changes have offsetting effects on capital costs. The fall in marginal tax rates will increase the after-tax income generated by assets, lowering the cost of capital. However, for farmers who borrow to purchase capital equipment, a lower marginal tax rate will reduce the value of interest deductions. Nevertheless, the overall effect of the marginal tax rate reduction will be to lower the cost of using capital.

The new depreciation rates, which will be more accelerated than in the existing law, are also spread out over longer recovery periods.

Under the existing tax law, the farmer who purchased a tractor was eligible for the investment tax credit, as well as depreciation deductions taken over a 5-year period. Under the new law,

1986 Asset type	Cost per dollar of the purchase price			Change
	Current law	New law	Dollar	
<b>1986</b>				
Tractors	\$0.3058	\$0.3356	9.71	
Long-lived equipment	0.2152	0.2372	9.73	
Single-purpose structures	0.0945	0.1038	9.76	
Crop storage structures	0.1368	0.1502	9.74	
Multipurpose structures	0.1108	0.1108	0.00	
<b>1987</b>				
Tractors	\$0.3058	\$0.3337	9.09	
Long-lived equipment	0.2162	0.2368	9.52	
Single-purpose structures	0.0945	0.1058	11.90	
Crop storage structures	0.1368	0.1512	10.52	
Multipurpose structures	0.1108	0.1106	-0.15	

\*Capital costs are normalized on asset prices. Inflation rate is assumed to be 3 percent in both 1986 and 1987. The nominal before-tax interest rate is assumed constant for both years. Asset prices are also assumed to be constant. The capacity of assets is also assumed to depreciate at a rate equal to the 200 percent declining balance method.

### Machinery Depreciation Under Current and New Law

Year	Percent of asset cost		Actual deduction	
	Old ACRS	New ACRS	Old ACRS	New ACRS
1	15*	14	\$3,000	\$2,800
2	22	25	4,400	5,000
3	21	17	4,200	3,400
4	21	13	4,200	2,600
5	21	9	4,200	1,800
6	--	9	--	1,800
7	--	9	--	1,800
8	--	4	--	800

\*Eight-percent tax credit is also available in year 1.

the investment tax credit is repealed and the tractor must be depreciated over a 7-year period. However, depreciation deductions are larger during

the early years of the 7-year period. (James H. Hauver, James Hrubovcak (202) 786-1458, and Ron Durst 786-1290)

the remainder. As expected, cash grain farms received the largest share of program payments, about 62 percent, while cotton farms received 10 percent.

Among livestock farms, cattle, hog and sheep operations received about 14 percent of all Government payments, while dairy farms received about 9 percent. In view of increasing Government crop payments to agriculture, it is not surprising that livestock

producers who also grow crops are participating in crop commodity programs.

Just as crop farms had a larger share of livestock receipts in 1985 than in 1982, they also had larger shares of feed expenses and livestock purchased for resale. But, the distribution of seed, fertilizer, energy, labor, and custom work expenses between crop and livestock farms in 1985 was nearly identical to that reported by the Census for 1982. The 1985 survey data

indicate that crop farms had 75 percent of the rental expenses, primarily for land, and 50 percent of property taxes. Interest expenses tended to be evenly distributed among crop and livestock farms. (Jim Johnson and Mary Ahearn (202) 786-1807)

## INCOME BY TYPE OF FARM

The 1985 Farm Costs and Returns Survey and the U.S. aggregate farm income and expense estimates were used to develop estimates of 1985 income for all crop, all livestock, and nine specific farm types. The 1986 forecasts of U.S. income and expenses (and their components) and the 1985 distributions of income by type of farm from the FCRS were used to develop the 1986 projections for each farm type.

**Crop farms.**—In 1985, crop farms' cash receipts totaled \$72.8 billion, over one-half of the \$142 billion for all farms. However, crop farms took three-quarters of the \$7.7 billion in Government payments. Crop farms had cash income of \$26.7 billion, about 60 percent of total cash income. Cash income for the 965,000 farms producing primarily crops averaged \$27,000 per farm.

Net cash income is expected to fall to approximately \$25,000 per farm in 1986, because of a 13-percent decline in cash receipts. Government payments to crop farms will rise more than 60 percent, cushioning the fall in commodity prices. Lower expenses should save crop farms more than \$3 billion in 1986.

Net cash income is projected to be down over 2 billion for cash grain farms. Lower production and prices for all major cash grains have been more than offset by a \$2-billion drop in cash expenses and a \$3-billion gain in Government payments. Direct payments to participants in the 1986 corn, wheat, sorghum, and barley programs increased 106, 66, 97, and 126 percent, respectively. Cash grain operations have received more than \$13,000 per farm in Government payments in 1986.

Net cash income is decreasing about \$4,000 per cash grain farm in 1986, and about \$5,000 per tobacco and cotton operation. Lower production and prices for cotton and tobacco were offset by Government payments of more than \$9,000 per farm in 1986.

Income per vegetable, fruit, and nut farm is forecast up slightly in 1986, and nursery and greenhouse incomes

## Distribution of Production Expenses Between Crop and Livestock Farms

1/ FCRS = USDA's Farm Costs and Returns Survey. NA = Not applicable.

are projected to increase more than a tenth. These farms are the only crop category to experience higher income in 1986. The larger size of these specialized operations has continued to generate much higher net cash income per farm than among the more traditional cash grain, cotton, and tobacco operations.

The overall decline in 1986 crop-farm cash incomes is not unusual given the wide fluctuations that often occur in agricultural incomes. However, the magnitude of the underlying factors—principally large price declines, large expense declines, and offsetting large increases in Government payments—is much greater than has been typical in the 1980's.

**Livestock farms.**—Returns to the livestock sector are improving in 1986. The ratio of livestock to crop net cash income per farm illustrates this turnaround: the ratio increased from 48 to 66 percent between 1985 and 1986, propelled by a 20-percent increase in net cash incomes of livestock farms.

Cash receipts and gross cash income are strengthening for the livestock sector because of price increases for cattle and hogs and record production in dairy and poultry. Government payment levels on beef, hog, and sheep operations that also grow grain will increase to \$1.0-\$2.0 billion in 1986 (from \$1.2 billion in 1985), becoming an important component of livestock producers' cash income. Declines in cash expenses are projected to occur for every livestock type, also providing an important income boost.

## Net Cash Income Rising on Livestock Farms, Falling on Crop Farms

More than 1.3 million farms raised primarily livestock in 1985, and they averaged about \$13,200 in cash income each. Higher prices, production, and Government payments, combined with lower expenses, will increase average livestock farm incomes to more than \$16,000 in 1986. This 24-percent gain is one of the largest in recent years, and will provide substantial relief to beef, hogs, sheep, and "other livestock" farms. Per-farm income gains for dairy and poultry should be near 20 percent as well. *(Richard Kold and Greg Hanson (202) 786-1804)*

## SPECIALIZED FARMS' NET RETURNS IN 1985

This article compares the before-tax business profitability of five specialized farming operations<sup>1</sup>, using different net returns concepts, for major

<sup>1</sup>Specialized farms are defined in this analysis as having production value of \$40,000 or more, and more than half of their production in one commodity (with one exception: corn and soybean production were combined because they are commonly jointly produced). The smaller farms are eliminated because they are more likely to receive most of their farm income as the imputed rental value of their farm dwelling. The proportion of production accounted for by specialized farms varies by commodity. In general, dairy, cotton, and rice production is more concentrated on specialized farms than wheat or corn-soybean production.

production regions of the country. It is based on calendar 1985 data from the Farm Costs and Returns Survey. In-kind farm housing income and income tax effects are ignored.

Farms are unique in that they are businesses that usually provide a residence for the proprietor. About 80 percent of farm operators reside on their farms. Along with the business returns from commodity production, the in-kind income from farm housing is an important return to closely held farm family businesses.

The importance of this in-kind income, as well as the high economic and social costs of relocating, helps explain why farm households may be willing to continue farming through periods of very low business returns. Quite often business and household needs for cash are met with off-farm income. Not only do most farm households receive some off-farm income, but the majority earn more off their farms than on.

Major variations in farm accounting come from differences in (1) the consumption of farm capital, (2) the treatment of inventories, (3) the farm income and expenses generated by the farm household as separate from the farm business, and (4) the paid and unpaid labor and management time of the farm household in the farm business.

In calculating net returns for specialized farms, the net returns concept excludes depreciation but includes actual capital expenditures; includes the value of crops produced in 1985 but not sold; excludes all farm household items; and includes net returns both with and without an imputation for the expense of unpaid operator and household farm labor. (See the accompanying box for a comparison of this concept with the standard USDA farm income concepts.)

Average net returns for a particular commodity will be affected by the farm structure typical for that commodity. For example, rice production is concentrated on fewer and larger farms than dairy production, which occurs on

all sizes of farms. The greater the investment in productive capacity per farm, the greater the expected returns, other things being equal.

Survey data are not sufficient to permit an analysis of returns by size classes for the five farm types. However, the proportion of operations with positive net returns in 1985 is also reported to provide an indicator of profitability, although it does not take size into account.

**Wheat farms.**—Wheat production is largely concentrated in three regions of the country: the Central, North Central, and Northwestern. Kansas, Oklahoma, Texas, Colorado, and Nebraska—the Central States—account for about 40 percent of U.S. wheat production. Almost three-quarters of the wheat farms in this region had positive net returns in 1985. Net returns for all specialized wheat operations in this region averaged \$25,071 per farm.

The more northern Central States (North Dakota, South Dakota, Montana, and Wyoming) had a slightly lower average return, but a higher percentage of operations earned positive net returns.

The Northwestern wheat-producing area—made up of Washington, Oregon, and Idaho—accounted for only about 12 percent of U.S. production. Farms here had the highest average return of the three wheat regions, \$29,696 per farm, but the lowest proportion of operations with positive net returns. The Northwestern wheat region includes more large operations than the other two, thereby raising the average return for the region.

When an imputation is made for the labor expense represented by the operators' and household members' work on the farm, the rankings of average net returns by region do not change, although the proportions of positive net returns are all considerably lower.

**Rice farms.**—Texas and the Delta States (Arkansas, Louisiana, and Mississippi) produce about 86 percent of U.S. rice. Three-quarters of the rice producers in this area are specialized farms (having \$40,000 worth of production and the majority from rice).

Farm Production by Region and Crop, 1985

Commodity and production region	Regions' share of U.S. sales	Specialized farms' share of regional production	Without imputation for own labor		Net returns	
			Average <sup>a</sup>	Percent with positive returns	Average <sup>a</sup>	Percent with positive returns

<sup>a</sup>The average net returns are for all farms, not just those with a positive net return.

Sources: Farm Costs and Returns Survey, 1985.

## Farm Income Concepts Vary

Net returns not including unpaid household labor are calculated as:

Gross Income  
 Value of crop production (less that fed to livestock)  
 Livestock sales  
 Fuel, electricity  
 Direct Government payments  
 Other farm-related cash income  
 Value of farm production consumed on farms  
 Farm wages paid to operator & household  
 minus  
 Business expenditures  
 Feed, livestock, seed  
 Fertilizer, lime, pesticides

ever, for livestock, only sales data are available from the Farm Costs and Returns Survey. For this reason, net returns are not reported here for any livestock operations other than dairy.

Survey data also do not permit the calculation of depreciation of the farm machinery and buildings used up during production. Therefore, capital expenditures which are reported on the survey are used in lieu of an estimate of capital consumption. For the sector as a whole in 1985, depreciation was about 75 percent greater than capital expenditures (\$17.3 billion compared with \$10.1 billion).

Net returns including labor are calculated by imputing an expense for the unpaid hours that operators and their

household members work on their farms and subtracting this from the first net returns estimate. This is done because a farm household's time has a value equal to the wages that members could earn in other activities. Unpaid operator and household time is conservatively valued at the average wage rate for farm laborers.

The standard USDA farm income concepts—net farm income, net cash income, net cash flow, and net business income—differ from the net returns concept used here. They have many of the same individual gross income and expense items in common, such as all gross cash farm income and cash business expenses. However, they differ in several important respects as indicated:

### Major Differences Among USDA's Farm Income Concepts

Item	Net farm income	Net cash income	Net cash flow	Net business income
Treatment of farm capital	Includes depreciation expenses	None	Includes capital expenditures	Includes depreciation expenses
Value of the change in Inventories	Included	Excluded	Excluded	Excluded
Farm household accounts	Included	Excluded	Excluded	Excluded
Noncash items	Included	Excluded	Excluded	Excluded except depreciation
1985 U.S. estimate (bill.)	\$30.5	\$44.0	\$27.1	\$26.4

This concept is intended to provide a measure of business profitability. Therefore, the cash expenses and rental value of the farm dwellings are excluded.

The value of inventory change is included implicitly for crops because total crop production is valued. How-

On average, net returns for rice producers were a relatively high \$53,447 per farm in 1985. Even when an imputation is made for unpaid labor hours, net returns averaged over \$40,000.

**Corn and soybean farms.**—Over half of U.S. corn and soybean production combined comes from the Corn Belt (Illinois, Iowa, Indiana, Ohio, and Missouri). The Corn Belt had the highest average per-farm net return of all regions for 1985, both with and without an imputation for unpaid household labor. The Corn Belt also had the

largest percentage of operations with positive net returns—not only the largest of all corn-soybean regions, but also of all regions for wheat, rice, cotton, and dairy operations.

Corn and soybean farms in the Northern Plains States had a relatively high average net return as well, \$38,739 per operation. The Southeast had the lowest return for all corn-soybean regions, \$9,805. Including an imputation for unpaid labor, the average re-

turns for corn-soybean operations in the Southeast were negative.

The survey data permit a statistically reliable analysis of corn-soybean farms by size for the Corn Belt region. Farm size is measured by the value of total production. About 1.5 percent of corn-soybean farms in the Corn Belt have production valued at more than \$500,000, and the rest of the farms are about evenly split between the other two size categories of \$40,000-\$99,999 and

Cash Income of Livestock Farms, 1985 and 1986

Item	Year	Total, all farms	Total, livestock farms	Beef, hogs, sheep	Dairy	Poultry	Other livestock

Net cash income	1985	44	26.3	10.2	3.4	8.9	2.9	1.3
	1986	42-46	21-24	7-8	2-4	8-10	3-4	1-3
Farm numbers (1,000)								
	1985	2,275	965	586	136	98	35	111
	1986	2,214	940	570	133	96	34	108
Net cash income per farm (\$1,000)	1985	19.4	27.7	17.4	25.0	89.9	84.9	11.9
	1986	19-21	24-26	12-14	18-20	91-95	93-97	10-12

Value and Share of Production for Three Sizes of Corn-Soybean Farm in the Corn Belt, 1985

	Value of total production		
	\$40,000 - \$99,999	\$100,000 - \$499,999	\$500,000 or more
Share of region's farms (%)	48.8	49.7	1.5
Share of region's corn-soybean production (%)	22.6	68.4	9.0
Net returns before labor imputation			
Average (\$)	\$22,772	\$63,508	\$169,741
Percent with positive net returns	89.0	89.8	85.0
Net returns after labor imputation			
Average (\$)	\$12,370	\$48,753	\$152,906
Percent with positive net returns	75.6	81.5	83.6

\$100,000-\$499,999. As expected, the largest farms account for a disproportionately big share of production, 9 percent, compared with 68.4 percent for the mid-sized, and 22.6 percent for the smaller size class.

As farm size increases so does average net return. Before a computation is made for unpaid labor, the percent of farms with positive net returns is very similar among size classes. The largest farms had the lowest percentage of farms with positive net returns—85 percent. However, because a greater share of the labor on the largest farms is paid, when an imputation is made for unpaid labor expenses, the largest farms have the highest percent of farms with positive net returns, 83.6 percent.

**Cotton farms.**—About half of all U.S. cotton production occurs in the Delta States (Mississippi, Louisiana, and Arkansas) and the Southern Plains (Texas and Oklahoma). For statistical reasons, the samples for these two regions were combined. The average returns on specialized cotton farms were \$45,213 per farm. Over 70 percent of producers earned a positive net return. California and Arizona are also major cotton-producing States but again, because of sample size restrictions, estimates are not available for them.

**Dairy farms.**—Although dairy production occurs in every region of the country, the majority is in the Lake States, the Northeast (especially New York and Pennsylvania), and the Pacific region. The average net returns per farm in the Lake States were \$22,572; in the Northeast, \$24,539; and in the Pacific region, over \$40,000. The Southeast led with \$57,276. However, a high percentage of dairy farms in the Southeast are large operations. Nevertheless, the Pacific region had twice as high a proportion of large farms as the Southeast and yet had a lower net return.

Because dairy production requires more labor than most other types of operations, the differences between net returns before and after factoring in unpaid labor expenses are greater than for the other farm types. In fact, after unpaid labor imputations are made, only the Southeast, the Pacific, the Northern Plains, and the Northeast had positive average net returns. (Mary Ahearn (202) 786-1801)

Upcoming Releases from the Agricultural Statistics Board

The following list gives the release dates of the major Agricultural Statistics Board reports that will be issued by the time the January *Agricultural Outlook* comes off press.

December

- 1 Egg Products
- 4 Dairy Products
- Poultry Slaughter
- 5 Celery
- 10 Crop Production
- 12 Turkey Hatchery
- Milk Production
- 15 Potato Stocks

- 31 Agricultural Prices

## The Roller Coaster Ride of the Input Industries, 1975-1985

The agricultural input industries, like farming, are in transition. Over the last several years, the farm chemical, machinery, and fertilizer industries have had to contend with declines in domestic planted acreage as well as financial stress within the farm sector.

The fertilizer and farm machinery industries appear to be facing the greatest pressures, as revealed by their extensive industry reorganizations. On a lesser scale, the U.S. farm chemicals industry is undergoing changes, but export demand for pesticides and the industry's pricing structure may have mitigated the effects of the farm sector's woes.

In 1985, U.S. farmers spent nearly \$21 billion, or almost 20 percent of all farm cash expenditures, on manufactured inputs, and another \$10 billion on capital items. The prices and quantities of manufactured inputs purchased are major influences on net farm income which is determined by subtracting farm expenditures from cash receipts.

The seed, fertilizer, farm machinery, and pesticide industries are largely responsible for developing and encouraging the adoption of new technology. Productivity gains for farmers, and eventually cheaper food for consumers, are fostered by new and improved machinery, services, and products. Furthermore, increased productivity enhances the U.S. position vis-a-vis foreign agricultural competitors. Unfortunately, greater reliance on purchased or nonfarm inputs leaves agriculture more vulnerable to outside influences, such as during the energy crisis of the 1970's and the agricultural credit crunch of the 1980's.

### Input Indicators

Indicator	Average of annual changes	
	1975-81	1982-85
	Percent	
Agricultural exports (value)	11.1	-7.8
Planted acres (1982-86)		
Corn	1.2	0.1
Cotton	2.1	-4.8
Soybeans	4.0	-1.6
Wheat	3.5	-3.9
Other crops	-0.3	-0.4
Total principal crops	1.6	-1.8
Irrigated acres 2/	3.2	0.3
Index of crop prices received	2.2	-2.2
Index of prod. items prices paid	8.6	0.7
Per acre land values index	13.0	-5.0
Farm sector equity	12.1	-8.1
Real PCA interest rates 3/	1.3	10.5
Net cash farm income (nominal)	-0.1	7.8
Total agricultural debt		
Real estate	13.3	0.1
Non-real estate (excludes CCC)	13.3	-0.2

1/ Less than 0.5 percent. 2/ Estimated.

3/ Average rate, not percent change. Production Credit Association rate deflated by Producer Price Index.

Changes in agricultural production are quickly transmitted to the input industries. Planted acreage is perhaps the most critical factor in determining total consumption of fertilizer, pesticides, and seed. Durable inputs, such as farm machinery, are consumed over several years. Hence, decisions on them are often postponable and are more heavily influenced by such factors as a producer's farm equity position, farm income, and interest rates.

### *In 1970's, Growing Exports and Acreage Encouraged Input Industries To Expand*

The expansion of agricultural production during the 1970's and the subsequent contraction during the 1980's largely explain the current plight of the input sector. Spurred by record export growth from 1975 through 1981, planted acreage of the principal crops increased an average of 1.6 percent per year. Input-intensive corn acres grew an average of 1.2 percent per year from 1975 through 1981. During the same time, wheat, cotton, and soybean acreage grew from 2 to 4 percent annually.

Irrigated acres, another indicator of intensive input use, grew over 3 percent annually during the 7-year period. Crop prices received by farmers were increasing an average of 2.2 percent per year. In conjunction with the economy-wide inflation of the late 1970's, the expanding agricultural sector absorbed input price rises of nearly 9 percent an-

nually during 1975-1981. Nominal land values rose 13 percent annually, and lenders were liberally financing the growth of real estate and other farm debt.

In sum, the 1970's gave the input industries signals to add capacity and employment, and in some cases the signals were reinforced by growth in the export market for inputs.

#### *In the 1980's, Less Acreage, Higher Interest Hurt Input Manufacturers*

Despite some spectacular gains in net cash farm income, primarily from Government programs and reduced production costs, 1982-85 brought reversals in agriculture. Exports dropped off, land values began falling at rates not seen since the 1930's, and prices received by farmers declined over 2 percent annually.

Average planted acreage decreased 1.8 percent per year between 1982 and 1985. Furthermore, 1983's PIK program, announced early in the year, idled nearly 60 million acres. By the time the program was announced, input production for 1983 was well underway and manufacturers and distributors were burdened with large inventories.

Trends in the U.S. capital markets in the early eighties brought changes in demand for durable goods, such as farm machinery. The low and sometimes negative real interest rates of the 1970's had given way to very high rates by 1981. Steep real interest rates, along with declining farm equity, led farmers to reduce real and non-real estate debt with their record cash farm income. Consequently, durable goods purchases fell dramatically.

#### *After 40 Years of Expansion, Fertilizer Use Began Falling in 1982*

U.S. plant nutrient use peaked in 1981 at 23.7 million tons, ending an almost continuous 40-year expansion. Lower acreage since 1981 has led to a drop in overall domestic fertilizer use. Application rates also have affected total fertilizer use. Application of some nutrients has begun to grow more slowly, and application rates have actually declined for some fertilizers.

Higher yielding crop varieties, more irrigated acres, and improved cultural practices have increased the potential for higher crop yields and created additional demand for fertilizer. However, the yield gain from an additional application of fertilizer is generally smaller than the increase from an initial application, which means farmers are approaching optimal per-acre application rates given input and output prices.

In the case of nitrogen, diminishing economic incentives slowed the growth in application rates during the late 1970's and early 1980's. For corn, phosphate and potash fertilizer application rates have actually declined since 1981.

Government acreage reduction programs, especially for corn, foster lower fertilizer prices as farmers demand less fertilizer and dealers lower prices to stimulate sales. This cycle has been the nemesis of the fertilizer industry, leading to excessive inventories, reduced production and profits, and the closing of fertilizer plants.

#### Fertilizer Indicators

Classifications (SIC) 1475, 2873, 2874, and  
2875. 3/ 1982-84. 4/ SIC 2873, 2874, and 2875.

In the last decade, the United States has become less competitive in the world fertilizer market. The energy price jumps during 1972-74 and 1979-82 raised production costs for U.S. nitrogen fertilizer producers, because they use large amounts of natural gas in the production process.

Consequently, in the 1980's nitrogen fertilizer imports increased as the value of the dollar grew relative to other currencies. Lower priced imports replaced U.S. products, forcing the U.S. nitrogen fertilizer industry to close high-cost production facilities.

The U.S. potash industry faced a similar situation. Potash imports have increased and exports have declined, resulting in the closing of U.S. potash mines.

Since the U.S. phosphate fertilizer industry is one of the world's low-cost producers, the problem of stagnating U.S. sales in the late 1970's was solved by increasing exports. However, the U.S. industry is now being challenged by Morocco, Tunisia, Jordan, and other countries.

#### *U.S. Farm Machinery Industry Concentrated on Larger Tractors*

The 1970's were an optimistic but transitional decade for the farm machinery industry. The favorable economic environment fostered a switch to large equipment, here and abroad. Consequently, equipment exports, industry investment, and the U.S. farm machinery trade surplus grew rapidly. Production of small tractors (under 40 hp) was increasingly left to the Japanese, while production of medium-size tractors (40-99 hp) was moved primarily to European plants of U.S. multinational firms.

North American tractor manufacturers continued to specialize in larger two-wheel and four-wheel-drive vehicles. Through the 1970's, price increases plus the shift toward

### Farm Machinery Indicators

Indicator	Average of annual changes

U.S. trade balance in farm machinery	56.4	-30.9

1/ Standard Industrial Classification 3523.  
2/ 1982-84.

larger machines generated a 6-percent annual expenditure increase for new and used tractors and farm equipment, reaching a record \$11.7 billion in 1979.

The early 1980's brought a dramatic turnaround in the industry—farm machinery expenditures declined 13 percent annually. Manufacturers' shipments of all types of machinery declined, as unit purchases of new equipment dropped precipitously. At the same time, imports from Japan and Western Europe (including those from U.S.-owned plants) began to narrow the U.S. farm machinery trade surplus and add further pressure to strictly domestic manufacturers.

Furthermore, the increased capacity and quality of some new U.S.-produced equipment, such as tractors and self-propelled combines, meant that the unit sales levels of the 1970's would not be matched in the early 1980's.

In response to declining demand, increased imports, and continuing shifts of manufacturing overseas, the U.S. industry's employment dropped more than 11 percent per year after 1981. New capital expenditures in the industry declined, on average, 27 percent annually. These factors forced major reorganizations within and between companies, as the industry worldwide adjusted to declining demand.

### Pesticide Indicators

Indicator	Average of annual changes

### Lower Acreage Cut Pesticide Use

The chemical industry in general and the pesticide subsector in particular are characterized by heavy emphasis on research and development (R&D). Patent protection, the rapid adoption of new products derived from R&D, pest resistance, and environmental and health concerns all encourage efforts to devise new herbicides, insecticides, and fungicides.

Farmers worldwide continue to adopt these chemical products—the more traditional pest control methods, such as crop rotation, hand weeding, and mechanical cultivation, are being deemphasized. However, in recognition of pesticides' sometimes detrimental effects on humans and the environment, they have become agriculture's most regulated input.

Like other input industries, pesticide producers and distributors enjoyed growing markets during the 1970's and early 1980's. Not only were acres planted increasing, but the share of the major crops treated with pesticides grew. In 1970, about 80 percent of corn and cotton acres and nearly 70 percent of soybean acres were treated with herbicides. By the early 1980's, nearly 95 percent of the corn, cotton, and soybean acres were treated. However, insecticide use, which depends on infestation severity and is more sparing than use of herbicides, has remained nearly constant since the early 1970's.

Like fertilizer and machinery sales, pesticide manufacturers' domestic sales dropped after 1981. The decline in planted acreage resulted in less pesticide use. Meanwhile pesticide prices generally remained unchanged or declined slightly.

Despite patent protection for some products, decreased demand has constrained prices, leaving total industry sales consistently below 1981 levels. However, materials protected by patents and with little or no competition may be able to maintain their prices and help recoup the extensive R&D costs of new product development, testing, and registration (see *Agricultural Outlook*, October 1986).

Overall, pesticide manufacturers have weathered the agricultural downturn better than the other input industries. For example, employment in the industry, while declining

between 1982 and 1985, has not matched the falloffs of other input industries. The rate of capital expenditures in the industry slowed between 1982 and 1985, but did not drop off as it did with the other input industries. New capital expenditures were needed to produce an array of new pesticide products and to minimize environmental risks at manufacturing sites.

The U.S. pesticide industry has also enjoyed a growing export trade. While several other U.S. inputs are moving toward a negative trade balance, pesticide exports have increased faster than imports since 1981, partly because of the United States' extensive R&D facilities and efficient, specialized plants. Furthermore, the U.S. industry's share of world trade in pest-control products has remained roughly constant over the last 10 years.

#### ***Inputs Industry Also Faces Environmental and Health Issues***

A number of environmental and health issues face the input industries and may lead to restrictions on input use. For example, evidence is mounting that intensive fertilizer and pesticide use has caused at least local contamination of aquifers. Iowa and Nebraska have issued drinking water standards for specific chemicals.

The new Federal legislation covering pesticide registration not only recognizes the drinking water problem, but also addresses the safe handling of pesticides, and the residues allowable in domestic and imported food. In addition, new machines or tillage practices may be required to minimize soil erosion and chemical runoff.

#### ***Agricultural Policy Alters Input Use***

Government programs have traditionally focused on acreage reduction as a way of cutting output when large surpluses accumulate. Historically, reducing planted acreage 10 percent reduced input use by 6 percent. Inputs were not reduced by the full 10 percent because typically farmers idled their less productive, less intensively farmed land. In addition, farmers often boost input use on the remaining planted acres in response to less uncertain, and often higher, commodity prices.

However, the 1985 Farm Act may eventually lead to reduced per-acre input use, for two reasons:

- program yields<sup>1</sup> have been frozen, ending the incentive to increase yields solely to increase future deficiency payments, and
- the commodity loan rate—the additional revenue realized by participating farmers for each additional bushel or pound produced—was reduced for 1986. The Farm Act allows for further support price reductions through 1990. On the other hand, expected input price declines will tend to offset input use reductions encouraged by lower commodity prices.

<sup>1</sup>Farm program yields for crop years 1986 and 1987 are the average yields on a farm during 1981-85 excluding the high and low years.

While farmers are compensated for reducing their production and sales, the input industries are not. However, two Government actions have at least acknowledged the effects of major acreage reductions on input suppliers. In the first, a Small Business Administration program was established in response to PIK. The program allowed small- to medium-sized input manufacturers or distributors suffering severe economic hardship because of the PIK program to receive low-interest recovery loans.

The second action, in the 1985 Farm Act, mandates that the total acres diverted in any county must be limited so as not to hurt the local economy. Hence, local input suppliers are protected from a massive loss in sales.

Neither a low-interest loan nor acreage base protection prevents economic hardship or even bankruptcy among input industries. However, the new Farm Act mandates early announcement of farm program provisions, which should allow input manufacturers to make a more orderly preparation for the upcoming planting season.

#### ***Outlook Continues Cloudy***

In retrospect, increased demand for domestic agricultural inputs in the 1970's encouraged many of the affected industries to overexpand. Many industries added capacity, employment, and inventory in anticipation of long-term demand growth which did not materialize. The result was that many industries had to contract during the 1980's.

The short-term outlook is for continued build-up of agricultural stocks, and perhaps only modest revival of foreign demand. This outlook suggests that capital and labor will continue being encouraged to shift out of both agriculture and the input industries. [Stan Daberkow and Paul Andrilenas (202) 786-1456]

## How Altering Farm Production Levels Affects GNP and Employment

Natural disasters, changes in domestic or export demand, world crop shortages, and changes in Government policies are among the events that can shock the agricultural economy. These shocks can change agricultural production and its demand for production inputs. A small shock may be felt just in the agricultural sector. But, a much larger shock, involving the economic and employment patterns that link agriculture with the entire economy, may be felt throughout the U.S. economy. Analysis of the economic and employment linkages helps show how they can transmit shocks throughout the economy.

### *Upstream and Downstream Linkages*

The farm sector is linked to the larger economy in a network of input purchases and product sales. Farms buy inputs such as equipment, supplies, feed, seed, fertilizer, labor, and financing from what can be termed "upstream" sectors. In turn, farms sell their products to "downstream" sectors which store, process, transport, manufacture, distribute, retail, consume, or export the products. For some commodities, like cotton, these chains are very long. Cotton may be ginned, spun into thread, woven into fabric, manufactured into garments, and sold in retail stores. For grain destined for storage or export, however, the chain can be short, ending with transport to a central terminal or port.

Agriculture is only one segment, not a dominating force, in this network of industries. The agricultural sector can purchase inputs and sell its own products only because there is a demand for the final products that will be made from them. The farm sector cannot unilaterally increase its output and expect to proportionally increase activity in the rest of the economy. This could occur only if agriculture were the only factor limiting the output of the economy. This has seldom, if ever, been true; agricultural production

has generally been in surplus. Since the excess is normally stored by farmers or the Government, farm production can usually be cut, within limits, without proportionally reducing activity downstream.

In addition, the linkages are driven mostly by the volume of output from agriculture, not the value. Changing agricultural commodity prices without changing volume produced would not directly affect either output or employment in the rest of the economy.

Although the viewpoint of this analysis is national, local economies can be seriously affected by changes in the farm sector, depending on their specialization in farming, input supplying, or product processing.

Changes in the structure of U.S. agriculture over the last two decades have strengthened the ties between farming and the general economy. For example, purchased inputs increased from \$51 billion in the early 1960's to \$81 billion (in constant 1982 dollars) in the early 1980's. Also, far more value is now being added to agricultural products after they leave the farm. The value added in downstream industries rose to \$440 billion (in constant 1982 dollars) in the early 1980's, from \$235 billion in the early 1960's.

### *The Dollar Measure of Linkages*

The linkages of the food and fiber system to the larger economy are shown in figure 1. The \$648 billion in final consumer, export, and stock demand for farm products reported in 1984 was made up of \$518 billion in downstream activities, \$66 billion in on-farm activities, and \$65 billion in upstream activities.

Looking at this flow so as to focus on the farm sector, \$1.00 in farm activity was linked upstream to \$64 in input activity and downstream to \$3.20 in further-processing activity if the product in question was ultimately consumed domestically. However, if the product was exported raw, this same \$1.00 in farm activity was linked to only \$31 in downstream activity. The downstream amount was negligible if the commodity was stored by the farmer or Government as surplus.

The statement that agriculture accounts for 18 percent of the United States' GNP refers to the entire complex of agribusiness activities from the beginning to the end of the stream. Farming alone accounts for 2 percent of total GNP, while upstream activities account for another 2 percent and downstream activities for 14 percent.

Describing these same linkages in employment terms, the 21.0 million jobs involved in meeting consumer and export demand and storing surplus farm products in 1984 were comprised of 16.3 million jobs downstream, 2.7 million jobs on the farm, and 2.0 million upstream.

The accompanying table illustrates these linkages in more detail. Domestic food expenditures of \$450 billion in 1984 required supporting farm-sector output<sup>1</sup> of \$140 billion, generated nearly \$44 billion of farm-sector GNP, and required nearly 2 million farm workers. Upstream industries serving this farm sector output accounted for \$96 billion in total output, \$54 billion in GNP, and employment of 1.7 million people.

<sup>1</sup>Because output measures total sales, it includes some double counting. GNP eliminates double counting of crops' value as they move downstream.

### The Cost of Farm Programs: Reading the Fine Print

Price support and related outlays for program commodities cost an estimated \$25.8 billion in fiscal 1986, leaving many observers wondering whether there is a less costly way to support the U.S. farm sector. Both during and after debate on the 1985 farm bill, several alternative programs were introduced featuring lower Government outlays and higher levels of support. These alternatives were rejected mainly because analysis showed them to be more costly than the Food Security Act of 1985. Yet some of the alternatives showed no direct payments made to the farm sector. How can a farm program without direct payments be more costly than one with direct payments?

For 50 years, U.S. farm policy has embraced a core objective of providing support for farm income, generally accomplished through supporting farm prices. There are two ways to raise farm prices: increasing demand for farm products or reducing supplies. What makes some farm programs more costly than others is the method of supporting farm prices. Raising farm prices by stimulating demand for commodities generally results in visible outlays, such as export subsidies. Depending on the degree of support provided, these visible outlays can become quite high.

Supporting farm prices by reducing supplies, on the other hand, appears less costly; if supplies are reduced enough, farm prices rise sufficiently that supplemental direct payments are unnecessary. But, as the article on linkages shows, the farm sector is highly dependent upon the non-farm economy for financial and physical inputs, and on foreign markets for a substantial share of its demand. Consequently, increases in farm prices resulting from supply reductions can impose large adjustments, and hence great costs, throughout the nonfarm economy. The difference is that the costs are hidden under a supply-reducing program.

To show how this occurs, consider a comparison between the current mix of programs provided in the Food Security Act, and a farm program that tries to provide income support at nearly the same level by supply restriction alone. The article on linkages describes this second program.

The Food Security Act allows for lower farm support prices based on moving averages of past market prices, but for the first 2 years, it freezes target prices at 1985 levels. Thus, as farm prices follow the decline in loan rates, the direct payments required to make up the difference between market prices and target prices increase. Through lower price supports and additional Export Enhancement provisions, the Food Security Act helps increase demand for farm commodities. Thus, the net effect of the Food Security Act is increased demand and visibly high program outlays.

Under a large acreage reduction (LAR) program, farm prices would be increased by making commodities scarce. Higher farm prices would make direct payments unnecessary. Foreign demand under the program would decline. And, given some price-responsiveness in the domestic market, significant decreases would also occur in domestic demand.

Thus, the first hidden cost imposed by a LAR program would be that domestic consumers would pay more for less food, and the cost of farm supports would be shifted from taxpayers to consumers.

Foreign consumers would lose in two ways. First, less production would be available for export from the United States. Export prices would rise. If foreign consumers continued importing from the United States, they could do so only at higher prices.

Second, suppose importers turned elsewhere for imports. If, previous to implementing a LAR program, the United States had been a major competitor in world trade of a commodity that was now priced much higher, the prices of competing exports would tend to increase along with the U.S. price. In effect, the United States would create a price umbrella which would allow competitors to increase their prices somewhat and still capture greater shares of world trade. Thus, even if foreign consumers turned away from higher priced U.S. exports, they would likely have to pay more for imports since the overall world price would increase.

If these were all the costs of a LAR program, however, many would still consider it feasible. With food expenditures currently claiming a relatively small share of U.S. consumer expenditures—about 15 percent—some people feel that U.S. consumers do not pay their fair share for an abundant food supply. But a LAR program would be a regressive food tax, hurting low-income consumers who have less ability to accommodate food price increases.

A LAR program would have other hidden costs in addition to those imposed on domestic and foreign consumers. In fact, it would impose costs on every sector or industry with which production agriculture is linked, and even on agriculture subsectors that do not have oversupply problems—such as livestock and poultry producers. Because feed is a major component of the cost of producing beef, pork, poultry, and dairy products, producers of these products would feel the brunt of a LAR program immediately. Costs would ultimately be transferred to consumers.

A LAR program would also have swift consequences for input industries. Farmers naturally would need fewer inputs, such as seed, fertilizer, and pesticides. The industries that rely on farm demand for these inputs would have to contract. Services demanded by farmers would also decrease.

The accumulated effect of a LAR program can be measured in terms of jobs lost and reduced economic activity. Because of the linkages between agriculture and the rest of the economy, the substantially reduced volume moving through the system reduces total economic activity by about \$65 billion. This is more than double the amount of direct payments made to farmers in fiscal 1986.

Furthermore, some direct payments would still occur under a LAR program. High food prices would add pressure for increasing food stamp benefits. Unemployment increases claims for unemployment benefits until alternative jobs can be found. [Barbara Stucker (202) 786-1869]

Downstream linkages serving domestic food demand accounted for \$741 billion in total output, \$331 billion in GNP, and 10.4 million jobs. Domestic food expenditures are the largest final use category. The others in descending order are nonfood agricultural products (shoes, clothing, tobacco, flowers, seeds, and potted plants), agricultural exports, and storage of agricultural stocks. Agricultural imports reduced the demand for domestic farm products by \$31 billion. The farm sector and the economy can be affected very differently depending on which demand sources are affected by a shock or policy change.

#### Effects of Shocks

How an economic shock or policy change in agriculture reverberates throughout the economy depends on several factors:

- the strength of the linkage,
- the size of the economic shock or policy change,
- how the policy change is implemented (for example, restricting crop acreage, versus restricting total production, versus restricting marketed output), and
- the dependence of local economies on the farm sector and farm-related industries.

There is an order in which different parts of the total agricultural sector would be affected by an economic shock or policy change. Small changes would affect only storage by farmers or Government. Larger changes would start to affect farm production and input use. Still larger changes would affect exports of farm products. But, very large changes would be required to affect domestic processing, distribution, and consumption of farm products.

Similarly, small changes might have little effect on long-run farm prices, but larger changes would have progressively larger effects as more price-responsive parts of the food and agricultural system were affected. If a change or shock were large enough to be felt all the way to the domestic processing and consumption end of the agricultural complex, then farm and food prices would have increased substantially.

How a farm policy or program change is implemented also can modify its effects on agriculturally linked sectors. Traditionally, most commodity programs have relied on voluntary acreage reduction programs to limit the land put into production. Such programs have generally not resulted in equivalent cutbacks in other agricultural inputs.

Output, GNP, and Employment for Final Uses of Farm Products, 1984

Final use category	Upstream linkages	Farm sector	Downstream linkages	Total linkages	Demand source
<b>Household food expenditures</b>					
Total output (\$ bil.)	96.2	140.1	740.9	NA	NA

Figure 3

### How a Large Acreage Reduction Program Would Change Agricultural Sector GNP and Employment

<sup>1</sup>Scaled to change in demand to correct for small errors introduced in calculation.

<sup>2</sup>Clothing, shoes, tobacco, cut flowers, seeds, and potted plants

However, if a farm program change were implemented through limiting production, or limiting the amount of commodity that could be sold, as with marketing quotas or certificate programs, the effects on agricultural input use could be much larger. Farmers would tend to use purchased inputs sparingly and use more owned inputs, such as land.

#### Farm Program Impacts

A quick look at two policy alternatives illustrates how these linkage measures are used.

- The first alternative is a small annual acreage reduction program designed to limit accumulation of excess stocks by Government. The program leaves long-run farm prices essentially unaltered.
- The second alternative is a large permanent acreage reduction program designed to significantly raise farm commodity prices.

A reduction of 30 million acres, about 10 to 15 percent of the total program acreage, would be roughly equal to the average of the programs in effect over the last two decades. Most of the acreage reduction would come from wheat and feed grain area cuts, with smaller cuts in cotton and rice. This voluntary reduction is assumed to be implemented only to minimize excess production that would otherwise end up as Government surplus. As a result, the impact on the final demand for farm products is limited to changes in stocks.

With no changes in consumer or export demand, overall economy-wide impacts are relatively small and fall mostly on the farming and input industries. As demonstrated in figure 2, a 30-million-acre reduction would reduce final stock demand \$9 billion, on-farm activities \$6 billion, input industry activity \$3 billion, and downstream activities \$1 billion. The employment impacts of the program would be largely limited to the same industries—affecting 315,000 jobs in farming, 162,000 in input industries, and very few jobs downstream.

Alternative 2 is a 125-million-acre reduction program aimed at balancing supply and use at significantly higher commodity prices—about 80 percent of parity. Its impact would be substantially larger. It would require idling roughly 50 percent of the program acreage base and raising farm prices 30 to 40 percent above 1985/86.

The full range of economic linkages would be affected in this situation. A 30- to 40-percent rise in farm prices would raise consumer food prices nearly an equivalent amount. Consumers, over time, would adjust their food purchases—buying fewer high-value products such as red meats, dairy products, and highly processed food, and substituting lower value products such as vegetables, potatoes, and grains.

Because of these food substitutions, total consumer food expenditures would not increase as much as the increase in prices, and the result would be a 10-percent decline in the value-weighted volume of food consumption. Similarly, export demand could drop 30- to 40-percent in response to the increase in farm prices, and stocks would be reduced to current needs, essentially eliminating the excess stock demand.

## Limitations to the Analysis

The GNP and employment impact estimates in the accompanying analysis are subject to a number of qualifications. First, they are measured relative to a base situation that assumes full use of our agricultural production capacity. In fact, the farm sector has operated at less than full capacity for 7 out of the past 10 years. Hence, part of the losses noted are hypothetical, because the economy has already absorbed them in arriving at the current level of income and employment.

Second, unlike the industrial sector, farm sector employment does not increase or decrease as output levels change. Thus, a substantial part of the employment change in the farm sector is more likely to be felt as underemployment of farm operators and their families than as a loss of jobs.

This study is based on input/output relationships in the national accounts maintained by the U.S. Department of Commerce. These relationships portray the structure of the economy for 1977. The national accounts measure the output of the economy (GNP) in terms of sales of products for final uses—domestic household consumption, investment, Government expenditures, and net foreign consumption.

The accompanying analysis focuses on the agriculture-related expenditures in this system—domestic household expenditures for food and nonfood, agricultural exports, agricultural and apparel imports, farm inventory changes, and Government purchases of farm commodities. The relationships between farms and farm-dependent industries are quite stable over time even though the level of economic activity in various industries changes from year to year.

Using these relationships, output, GNP, and employment estimates are projected to 1984 by correcting for the changes in prices and labor productivity that occurred in each of the industries since the base year.

The estimated relationships are subject to several limitations. First, the analyses of the effects of farm programs can only compare situations "with" versus "without" an economic shock or change in agricultural programs. Moreover, these comparisons show only the effects after the farm sector and the economy have had several years to adjust to

As a result of the drastically reduced volume moving through the system, downstream activity would drop by \$35 billion, on-farm activity by \$18 billion, and input industry activity by \$12 billion. Corresponding employment impacts would be the loss of 1.1 million jobs in processing and marketing, 660,000 jobs on farms, and 415,000 jobs in inputs industries—a total of nearly 2.1 million jobs lost.

A 125-million-acre reduction has a disproportionately larger nonfarm impact than a 30-million-acre reduction because all the downstream industries are involved, rather than just the input, farm, and storage sectors, which account for relatively little of the economy's total labor force and economic activity.

a sustained change in programs; they do not show the annual adjustments entailed in getting to the new situation.

Second, some assumptions necessary to the analysis may introduce errors. However, these errors tend to balance each other, and the resulting estimates are as correct as possible given current knowledge and analytic techniques. Three assumptions tend to overstate the adjustments the economy would make:

- The analysis assumes no redeployment of factors (labor, land, inputs). That is, it assumes that each industry or sector would continue to use exactly the same methods of production or proportions of inputs as before the policy change or economic shock. In reality, each sector can alter the mix of inputs it uses as conditions change.
- The analysis assumes no reemployment of factors released by a change in the level of economic activity. For example, labor displaced from a sector is assumed not to be re-employed in another sector. In reality, changing the use of factors from one sector to another is a second way that the economy adjusts in the long run to a change or shock.
- The analysis assumes that the prices of all goods and services in the economy remain constant relative to each other. In actuality, changing the relative prices of goods is a third way that the economy accommodates a change or shock.

Although these assumptions overstate economic adjustments, they are balanced by considering only direct changes in input, farming, and downstream processing activities. For example, this analysis ignores the drop in automobile sales that would be caused by lower employment in agriculture-related industries. These indirect linkages are strong throughout the economy and tend to balance the errors inherent in the previous assumptions.

Nevertheless, the input/output method of analysis, which is relatively accurate over 2 to 4 years, progressively loses accuracy for longer periods, especially for very large program changes. This is because more factors can be redeployed or reemployed and relative prices of goods and services can change over time in response to a large shock or policy change.

These linkage measures are subject to some practical limitations, but they do support several conclusions:

- The economy-wide impact of a large acreage reduction program on GNP and employment can, under some circumstances, overshadow their impacts on the farm economy.
- Small, annual farm programs, set up as temporary measures to limit Government accumulation of stocks, tend to have little employment and income impacts on the rest of the economy, but
- Large farm programs viewed as permanent measures to significantly raise farm prices affect the entire economy by causing cutbacks in industries linked to farm production.

1/ Retail costs are based on indexes of retail prices for domestically produced farm foods from the CPI-U published monthly by the Bureau of Labor Statistics. The farm value is the payment to farmers for quantity of farm product equivalent to retail unit, less allowance for byproduct. Farm values are based on prices at first point of sale and may include marketing charges such as grading and packing for some commodities. The farm-retail spread, the difference between the retail price and the farm value, represents charges for assembling, processing, transporting, and distributing these foods. 2/ Estimated weighted average price of retail cuts from pork and yield grade 3 beef carcasses. Retail cut prices from BLS. 3/ Value of carcass quantity equivalent to 1 lb. of retail cuts from pork and yield grade 3 beef carcasses. 4/ Market value to producer for quantity of live animal equivalent to 1 lb. of retail cuts minus value of byproducts. 5/ Represents charges for retailing and other marketing services such as fabricating, wholesaling, and in-city transportation. 6/ Represents charges made for livestock marketing, processing, and transportation to city where consumed.

Note: Annual historical data on farm-retail price spreads may be found in Food Consumption, Prices and Expenditures, Statistical Bulletin 736, ERS, USDA.

Information contacts: Denis Dunham (202) 786-1870; Ron Gustafson (202) 786-1830.

1/ Nominal values are percentage changes in currency units per dollar, weighted by proportion of agricultural exports from the United States. An increase indicates that the dollar has appreciated. 2/ Real values are computed in the same way as the nominal series, adjusted for CPI changes in the countries involved.

\*Preliminary; assumes the same rate of CPI increase/decrease as the previous six months. n.a. = not available.

Information contact: Edward Wilson (202) 786-1688.

# Order Direct and Save

Check these new, reduced subscription rates now offered on a user fee, cost-recovery basis from USDA's Economic Research Service.

**AGRICULTURAL OUTLOOK.** 11 issues annually averaging 52 pages. Subscribe from ERS for \$26 domestic; \$32.50 foreign. USDA's official outlet for farm income and food price forecasts. Data and discussion of issues ranging from international trade to prospects for commodity supply and demand, food marketing, agricultural policies, and other major issues affecting agriculture and the economy.

**FARMLINE.** 11 issues annually averaging 20 pages. Subscribe from ERS for \$14 domestic; \$17.50 foreign. Farm economic information in an easily read style reinforced with charts and statistics for those without time to review all the technical reports from ERS. Reports on all economic topics important to those involved in agriculture, with the focus on the causes and implications.

**NATIONAL FOOD REVIEW.** Quarterly averaging 40 pages. Subscribe from ERS for \$9.00 domestic; \$11.25 foreign. The latest developments in food prices, product safety, nutrition programs, consumption patterns, marketing, and processing technology for those who manage, monitor, or depend on the Nation's food system.

## How to Order

Check the box for each publication or insert the number of extra subscriptions you wish to order. Write one check or money order to cover total charges. You will receive a copy of the most current issue, and a letter acknowledging your subscription. *Do not send cash. No credit cards.* Sorry, no refunds. Foreign customers note: Only checks drawn on U.S. banks, cashier's checks, or international money orders accepted.

Publication	Domestic	Outside U.S.
Agricultural Outlook 11 issues	\$26.00	\$32.50
Farmland 11 issues	\$14.00	\$17.50
National Food Review Quarterly	\$ 9.00	\$11.25
